

Exception Handling

Errors -

Errors can be broadly categorized into two types. We will discuss them one by one.

- Compile Time Errors
 - Run Time Errors
-
- **Compile Time Errors** – Errors caught during compiled time is called Compile time errors. Compile time errors include library reference; syntax error or incorrect class import.
 - **Run Time Errors** - They are also known as exceptions. An exception caught during run time creates serious issues.

Exception Handling –

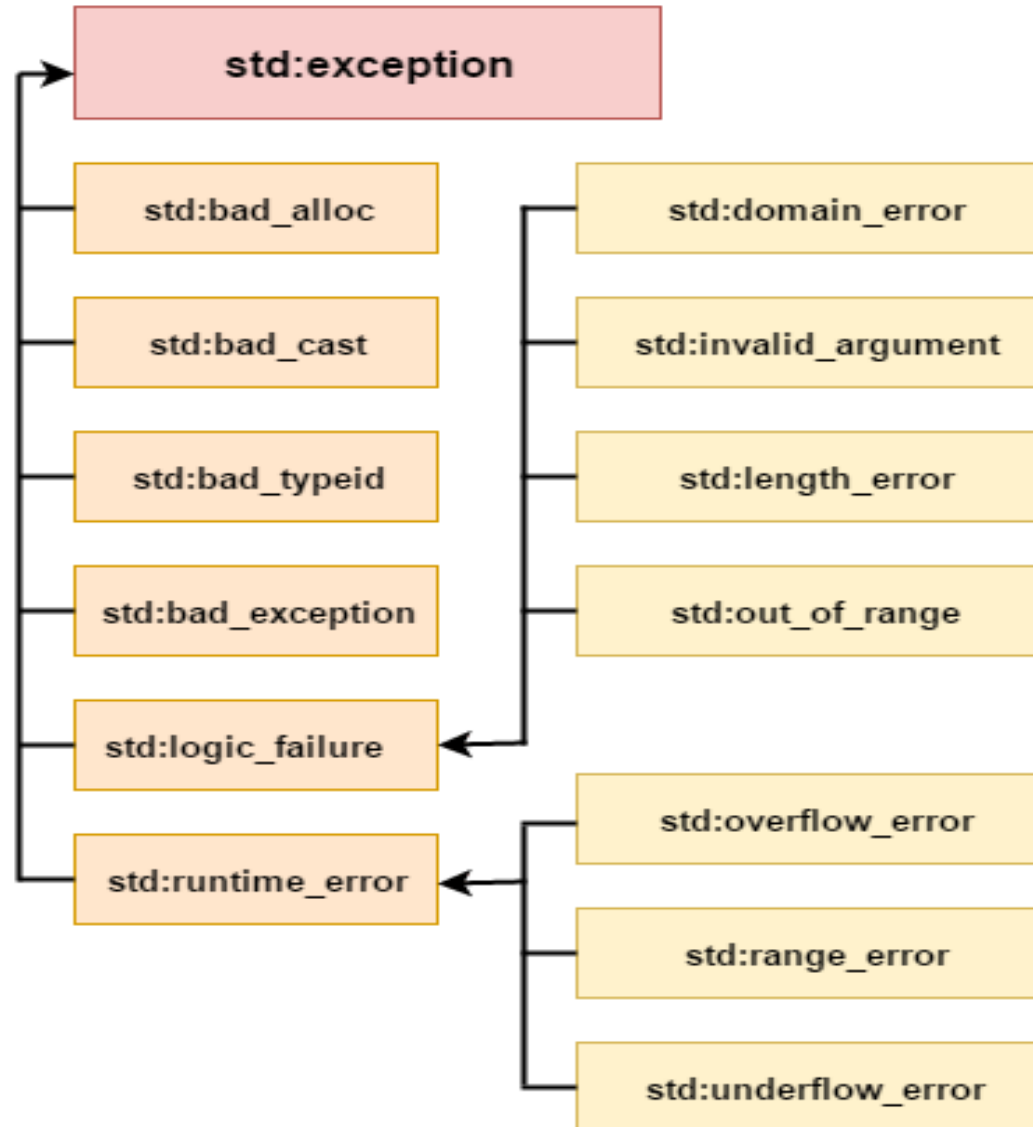

- Exception Handling in C++ is a process to handle runtime errors. We perform exception handling so the normal flow of the application can be maintained even after runtime errors.
- In C++, exception is an event or object which is thrown at runtime.
- All exceptions are derived from *std::exception* class. It is a runtime error which can be handled. If we don't handle the exception, it prints exception message and terminates the program.

Advantage - It maintains the normal flow of the application. In such case, rest of the code is executed even after exception.

Exception Classes -

In C++ standard exceptions are defined in **<exception>** class that we can use inside our programs. The arrangement of parent-child class hierarchy is shown below –

Exception	Description
<code>std::exception</code>	It is an exception and parent class of all standard C++ exceptions.
<code>std::logic_failure</code>	It is an exception that can be detected by reading a code.
<code>std::runtime_error</code>	It is an exception that cannot be detected by reading a code.
<code>std::bad_exception</code>	It is used to handle the unexpected exceptions in a c++ program.
<code>std::bad_cast</code>	This exception is generally be thrown by <code>dynamic_cast</code> .
<code>std::bad_typeid</code>	This exception is generally be thrown by <code>typeid</code> .
<code>std::bad_alloc</code>	This exception is generally be thrown by <code>new</code> .

❑ **NOTE:** In C++, we use 3 keywords to perform exception handling -

- 1) try
- 2) catch
- 3) throw

Try/catch Example -

```
#include<iostream.h>
```

```
#include<conio.h>
```

```
float division(int x, int y)
```

```
{
```

```
    if( y == 0 )
```

```
    {
```

```
        throw "Attempted to divide by zero!";
```

```
    }
```

```
    return (x/y);
```

```
}
```

```
void main ()
```

```
{
```

```
    int i = 25;
```

```
    int j = 0;
```

```
    float k = 0;
```

```
    try
```

```
    {
```

```
        k = division(i, j);
```

```
        cout << k << endl;
```

```
    }
```

```
    catch (const char* e)
```

```
    {
```

```
        cerr << e << endl;
```

```
    }
```

```
}
```
